

Abstract:

Biostratigraphic fossil field research (Lower Devonian, basing Upper Emsian, Emsquartzit) is summarized in this report about the Koblenz-area. In this region belonging to the Rhenish Schiefergebirge thick layers of quartzites were deposited in the beginning of the Upper Emsian substage. Only few fossil horizons with rich faunas proving normal marine shallow water conditions could be investigated. It can be presumed, that the visible field distribution of fossil horizons depends on paleogeographic facts. In the youngest Upper Emsian sand was deposited into the Mosel-trough, probably delivered by the Siegen-swell. Numerous outcrops show dominating thick quartzt layers resulting on changing sedimentary conditions. Heavy storms eroding older sediment, washed out all faunal assemblages. Other faunal elements may have been suffocated by sand masses when the storms were slackening. So it can be believed, that optimal living conditions for Emsquartzit-faunas were reduced only to few locations. The second part of this report contains investigations and remarks about the trilobite species *Digonus intermedius* (VIËTOR) and *Trimerus crassicauda* (SANDBERGER 1849), the Bivalvia species *Stappersella ladanensis* (FRECH), *Leptodesma (Peraptera) ladanensis* (FRECH), *Myalina (Myalina) circularis* (FRECH), *Myalina (Myalina) peltata* n. sp., *Rhenanomya tumida* (A. FUCHS) and the brachiopod species *Euryspirifer robustiformis* MITTMAYER. The brachiopod species *Adolfia prumiensis* (DREVERMANN) must be added to other valid index fossils of the basing Upper Emsian substage.

Liste der Emsquarzit-Fauna:**Vertebrata**

Lunaspis prumiensis (KAYSER) 2 Exemplare, Slg. GRÄSSLE, 10
